ACKNOWLEDGMENTS

The author wishes to gratefully acknowledge the following in making this dissertation possible:

The National Aeronautics and Space Administration for sponsoring this research;

Professor Furman W. Barton of the University of Virginia for his patience, encouragement, and constructive criticism throughout the preparation of this paper and my total Ph.D. program;

Dr. Ross L. Goble, Chief of Research Facilities
Engineering Division, for his motivational push, moral
support, and constructive criticism;

My management and fellow workers, especially Mr. John E. Doyle, for the opportunity to work and encouragement to finish;

Mr. Carl E. Gray, Jr. for helpful discussions, computer programming and figure preparation; Mr. Peter F. Jacobs, for programming; Mr. John T. Taylor for constructive ctiticism; and Miss Mary Morgan Cox and Mrs. Theresa C. Walker for help in preparing this manuscript.

And last, but certainly not least, the author also wishes to thank his wife, Jane, for her total encouragement and support before and during the course of the research and Jennifer, Todd, and Leslie - who make it all worthwhile.

ABSTRACT

The effect on stresses in a cylindrical shell with a circular penetration subject to internal pressure has been investigated. The research is limited to thin, shallow, linearly elastic cylindrical shells; however, some comparisons are made to thick shell experimental measurements. Results provide numerical predictions of peak stress concentration factors around nonreinforced and reinforced penetrations in pressurized cylindrical shells. Analytical results are correlated with published formulas, as well as theoretical and experimental/results. An accuracy study is made of the finite element program for each of the configurations considered important in pressure vessel technology.

A formula is developed to predict the peak stress concentration factor (SCF) for analysis and/or design in conjunction with the ASME Boiler and Pressure Vessel Code, Section VIII, Divisions 1 and 2. The formula is rationally derived to include all of the parameters that are required to define the various penetration configurations used in pressure vessel analysis, design, and construction. The accuracy of the empirical formula is determined by comparing to numerical, theoretical, and experimental data. In most cases, it is shown that the ASME Pressure Vessel Code SCF of 3.3 is extremely conservative.

CHAPTER I

INTRODUCTION

1.1 Statement of the Problem

In a cylindrical shell weakened by a hole, the stress distribution caused by an internal pressure load applied to the shell will differ considerably from that in an unweak-The maximum stress will be much larger if there is a circular hole in the shell than in the case where there is no penetration. This conjecture is suggested immediately by the case of a flat plate weakened by a hole with the plate stretched per unit length in one direction and with one-half of this stretch per unit length in the other direc-The maximum stress is 2.5 times the maximum stress in the solid plate. This factor (2.5) is known as the stress concentration factor (SCF). There is no reason to expect that the SCF is 2.5 for the shell. It depends on the geometry of the shell and the penetration: the curvature parameter of the shell, $\frac{\rho_a^2}{\rho_a}$ (ρ_a being the radius of the hole, which is a circle in the projected shell surface, R is the radius of the middle surface of the cylinder, and T, the shell wall thickness); the ratio of the diameter of the hole or pipe to the radius of the shell; and the ratio of the thickness of the pipe to that of the shell. (1)

most important feature of the stress state in the shell near the hole is that bending stresses occur, whereas in the unweakened shell only membrane stresses ($\frac{PR}{T}$ and $\frac{PR}{2T}$) are present.

The loaded hole boundary condition in a pressurized cylindrical shell with a membrane or diaphragm over the hole to contain pressure only has been investigated by many authors. (1,2,3,4,5,6) Another type of loaded hole boundary is the perpendicular intersection of two cylinders - shell and pipe. There are a few isolated numerical solutions (7,8,9,10) and some theoretical investigations. (1,2,11,12) There are many experimental results for both thin and thick shells containing nonreinforced penetrations (pipe only) (13 through 21) and very few for reinforced penetrations - pipe and pad (14,15,17,22,24) and pipe and pads. (23,24)

Also, the ASME Pressure Vessel Code (25) requires in a stress or fatigue analysis the stress concentration factor (SCF) to be not less than 3.3 for a "well designed penetration" in a cylindrical shell unless positive evidence is available to the contrary. This evidence usually means a separate analysis to confirm the peak SCF. This factor is primarily needed to obtain peak stresses to perform a fatigue analysis to predict the remaining life at a penetration in the shell or to assure that the peak stress

ORIGINAL PAGE IN OF POOR QUALITY around a penetration does not exceed allowable stresses. The need for a more refined and/or a more clearly defined stress concentration factor became apparent in validating the useful life of 91 penetrations in a cylindrical shell (38) located in a work/residential area of NASA - Langley Research Center. These penetrations in the shell range in size from 1-inch to 60-inches in diameter. There are a few formulas in the published literature (2,4,26,27) for a membrane over the hole or a very thin penetration (pipe), but none are applicable for reinforced penetrations in pressurized cylindrical shells.

The author and others were unsuccessful in obtaining any computer answers to an analytical finite element approach to the actual intersection curve of the shell, pipe, and pads boundaries. The compatibility equations for this actual curve, rather than a projected circular curve (uncovered during this study), were not acceptable to the computer program. Also, different coordinate systems for the shell and pipe input descriptions, solution vectors, and output notations were unsuccessful. Therefore, it was decided to abandon the analytical work and to magnetic particle examine and/or rework these penetrations rather than perform the analyses to obtain the refined stress concentration factors. This type of verification (field work in lieu of analysis) is not practical in all cases

since this shell which contains 91 penetrations is one of 1,600 pressure vessels (6000 pressure components) for which the structural integrity must be verified or validated in a five-year program at NASA - Langley Research Center. Thus, there is a need for a positive and clear definition of a well designed penetration to allow use of the 3.3 SCF or to obtain the appropriate SCF. A "proven" formula to approximate the peak SCF and/or a finite element program to obtain a refined SCF would be invaluable in validating shells, pipes and/or pad(s) configurations.

1.2 Object and Scope

The objective of this study is to determine the effect on stresses in a cylindrical shell with a circular penetration subject to internal pressure. The research is limited to thin, shallow, linearly elastic cylindrical shells; however, some comparisons are made to thick shell experimental measurements. Results from this study provide numerical predictions of the peak stresses around nonreinforced and reinforced penetrations in cylindrical shells. Analytical results are correlated with published formulas, theoretical and experimental results.

The present research also investigates the convergence and accuracy of different finite elements and mesh sizes. Finally, an approximate formula is developed to predict the

peak stress concentration factor for analysis and/or design in conjunction with the ASME Boiler and Pressure Vessel Code, Section VIII, Division 1 and 2. (25) The formula is rationally derived to include all of the parameters that are required to define the penetrations used in pressure vessel technology. The accuracy of the empirical formula is determined by comparing to numerical, theoretical, and experimental data. Since limited data is available for reinforced penetrations, many different configurations are pursued to supplement the published data to provide the restrictions to the formula. These configurations are modeled utilizing finite elements where compatibility between the cylindrical shell and the pipe/pad(s) are introduced through enforced constraint equations. The configurations investigated are for force and/or pipe around both nonreinforced and reinforced circular penetrations in cylindrical shells subject to internal pressure. For the force case, the penetration is considered to be covered by a diaphragm or membrane that allows the hole edge to deflect and rotate. It also transmits the pressure force to the shell in the form of a uniform transverse shear stress at the hole edge. An automation computer program which punches cards for these configurations for input to a finite element computer program (NASA STRUCTURAL ANALYSIS PROGRAM - NASTRAN⁽²⁸⁾) is utilized.

CHAPTER II

ANALYSIS

2.1 Matrix Analysis by Finite Element Methods

In the finite element method, it is necessary to obtain a characterization of the stiffness properties of each element in the structure and to relate end nodal displacements to the corresponding forces. This is expressed in the following form:

$$[K]\{u\} = \{F\} \tag{1}$$

where: [K] is the stiffness matrix

- {u} is the displacement vector
- {F} is the force vector

The process for generating a computer program of any structure that is composed of many finite elements is to first pick a set of local coordinates convenient for a typical element. The generalized element displacements are {\$\mathbb{E}\$} and forces are {\$\mathbb{F}\$}. The displacements {\$\mathbb{E}\$} and stiffness matrix [\$\mathbb{K}\$] are partitioned corresponding to ends i and j:

$$\begin{bmatrix} K_{\mathbf{j}\mathbf{i}} & K_{\mathbf{j}\mathbf{j}} \\ K_{\mathbf{j}\mathbf{i}} & K_{\mathbf{j}\mathbf{j}} \end{bmatrix} = \begin{bmatrix} \mathbf{s}_{\mathbf{i}} \\ \mathbf{s}_{\mathbf{j}} \end{bmatrix} = \begin{bmatrix} \mathbf{F}_{\mathbf{i}} \\ \mathbf{F}_{\mathbf{j}} \end{bmatrix}$$
(2)

In the process of connecting elements, it is found that one element's local coordinates are not the same as those for another element. Therefore, a set of system coordinates is chosen that is convenient for a system of elements and the local coordinate points are numbered (points 1, 2, 3, ...).

A systematic numbering process for the node points and members is chosen. The stiffness K_{ij} for each element is calculated in local coordinates where i and j refer to the end points of each element.

If the system coordinates or displacements are called $\{u\}$, the transformation from an element's coordinates to a system's coordinates is accomplished by a transformation matrix, $[\alpha]$. That is:

$$\{8\} = [\alpha] \{u\} \tag{3}$$

The stiffness of the element is transformed to system coordinates by use of Equations (3), (2), and (1).

$$[\overline{K}] = [\alpha]^{T} [K] [\alpha]$$
 (4)

Consider several elements that are connected. The next step is to generate the master stiffness matrix $\begin{bmatrix} K_{ij} \end{bmatrix}_M$ by summing all member stiffnesses in system coordinates. (29)

The compatibility equations for required coordinate points are introduced through multipoint constraint (MPC)

equations of the form:

$$\sum A_{j} u_{j} = 0 \tag{5}$$

where: A is the coefficient

u is the point

j is the degree of freedom

Thus, the stiffness matrix, force, and displacement vectors are modified by this degree of freedom link for each MPC Equation (5) at each grid point. (30)

After the compatibility equations are satisfied, the boundary conditions (displacements of the structure) are enforced through single-point constraints (SPC). Finally, the system applied external forces {F} are identified and the equation:

$$[K]_{R} \{u\}_{R} = \{F\}_{R}$$

$$(6)$$

is solved.

2.2 Formulation of the Problem

Consider a flat rectangular plate of thickness T containing a circular hole of radius ρ_a with its edges parallel to axes Y', Z' of the circular hole. A material point or finite element grid point within the plate may be located through cylindrical coordinates (ρ, ϕ, X) defined through

$$Y' = \rho \sin \phi$$
, $Z' = \rho \cos \phi$

(7)

Suppose that the plane Y' Z' is now rolled into a circular cylindrical shell in such a way that the Z'-axis becomes a generator of the cylinder and Y' a circular arc denoted by Y (see Figure 2.2.1). If R is the radius of the middle surface of the shell and 0 the angle in any normal cross section of the cylinder measured from the Y=0 plane in the positive direction of the Y-axis, then the following relationships are obtained to define the finite elements and grid points (see Figure 2.2.2):

$$Y' = Y = R\theta$$

$$R = R$$

$$\theta = Arc \sin \left(\frac{\rho \sin \phi}{R}\right)$$

$$Z' = Z = \rho \cos \phi$$
(8)

Consider that this same configuration - main (lower) shell (shown in Figure 2.2.1) with mid-surface radius R - is intersected by a branch (upper) shell with mid-surface radius ρ_0 and thickness t, ($\dot{\rho}_0 = \rho_a + t/2$), see Figure 2.2.3. The axis of the branch shell is normal to the axis of the main shell. Both shells are considered to be infinite in length and capped at their ends. Finally, consider that these two circular cylindrical

ORIGINAL PAGE IS OF POOR QUALITY

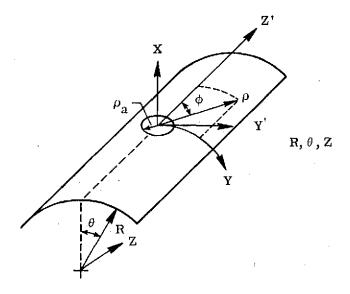

Figure 2.2.1.- Coordinate system for a cylindrical shell with hole.

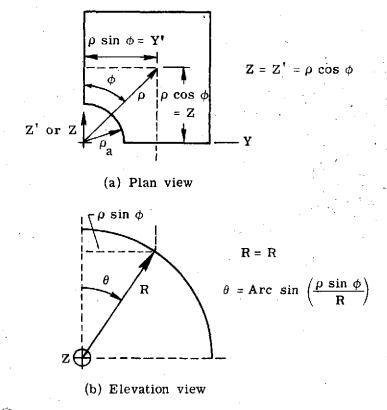

Figure 2.2.2.- Relationships used to define finite elements.

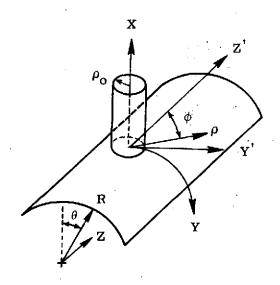

Figure 2.2.3.- Intersecting circular cylinders (pipe and shell).

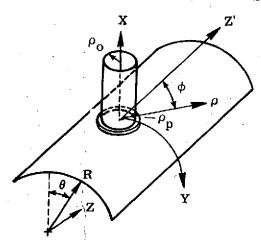

Figure 2.2.4.- Intersecting circular cylinders with reinforcing pad(s).

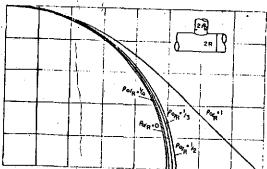

Figure 2.3.1.- Intersection curve of small cylinder with large cylinder when rolled out flat for various values of $\rho_{\rm O}/{\rm R}$.

ORIGINAL PAGE IS OF POOR QUALITY shells with mid-surface radii ρ_0 and R are complicated by the addition of one or two reinforcing pads with outside radius ρ_p and thickness t_p (see Figure 2.2.4). The location of the finite elements through grid points for a projected circular hole in a cylindrical shell with a pipe and pad(s) is governed by Equations (8).

2.3 Introduction of Compatibility Equations

The solution of these problems requires the matching of certain physical quantities (compatibility equations) along the intersection curve of the two shells and pad(s). When expressed in the cylindrical coordinate system, the intersection curve is of a very complex nature. Due to the difficulty of solving boundary value problems in which the boundaries are not situated on constant coordinate curves, the intersection curve can be approximated by $\rho_{\rm a}$, $\rho_{\rm o}$, and $\rho_{\rm p}$ equal to some constants, whenever $\rho_{\rm o}/R$ is small. Figure 2.3.1, indicates the error involved in this approximation when the lower shell surface is developed onto a plane. (11) It can be seen that the actual intersection curve does not differ appreciably from a circle, providing

$$\frac{\rho_{O}}{R} \leq 1/2 \qquad . \tag{9}$$

Therefore, the actual hole boundary is assumed to be circular, identical to that of a projected view of the penetration.

The compatibility equations for a pipe and shell configuration (Figure 2.2.3) are introduced through MPC Equations (5). The six equations for each grid point for both the shell and the pipe at the pipe and shell juncture at ρ_0 are as follows (Δ is deflection and θ is rotation):

where the subscript is the degree of freedom of the grid point. For the finite element analysis, the independent degrees of freedom are those for the shell, and the dependent dent degrees of freedom are those for the pipe. The superscript in Equations (10) denotes whether the degree of freedom represents the pipe or shell.

The compatibility equations for a "pipe-shell-inner pad" configuration (Figure 2.2.4) are as follows:

- 1. Pipe-to-shell juncture (ρ_0): Equations (10)
- 2. Inner pad (ip) to shell junctures for each grid point at both ρ_a and ρ_D :

$$\Delta_{R}^{ip} - \Delta_{R}^{shell} = 0$$

$$\Delta_{\theta}^{ip} - \Delta_{\theta}^{shell} - \frac{(T^{t}ip)}{2} (-\theta_{Z}^{shell}) = 0$$

$$\Delta_{Z}^{ip} - \Delta_{Z}^{shell} - \frac{(T^{t}ip)}{2} \theta_{\theta}^{shell} = 0 \qquad (11)$$

$$\theta_{R}^{ip} - \theta_{R}^{shell} = 0$$

$$\theta_{\theta}^{ip} - \theta_{\theta}^{shell} = 0$$

$$\theta_{Z}^{ip} - \theta_{Z}^{shell} = 0$$

The compatibility equations for a "pipe-shell-outer pad(op)" configuration for each grid point at locations ρ_{o} for the pipe and ρ_{a} and ρ_{p} for outer pad are as follows:

$$\Delta_{R}^{\text{pipe}} - \Delta_{R}^{\text{shell}} = 0$$

$$\Delta_{\theta}^{\text{pipe}} - \Delta_{\theta}^{\text{shell}} - (\frac{T}{2} + t_{\text{op}}) \theta_{Z}^{\text{shell}} = 0$$

$$\Delta_{Z}^{\text{pipe}} - \Delta_{Z}^{\text{shell}} + (\frac{T}{2} + t_{\text{op}}) \theta_{\theta}^{\text{shell}} = 0$$
(12a)

The compatibility equations for a "pipe-shell-outer and inner pads" configuration are identical to Equations (11) and (12). Each of these equations is provided as enforced constraints to every shell, pipe, and pad(s) connecting grid point.

2.4 Structural Analysis Computer Program

The finite element method is a modern, computer-orient-

ed approach to the analysis of structures. One of its principal advantages is its complete generality. This versatility makes it possible to consider arbitrary geometries, support conditions, loadings, and variations of material properties within the structures. The principal limitation is the cost of operation. The cost is incurred both in the time required to prepare the input data describing the finite idealization of the structure and its loading, and in the computer time required to obtain the solution. The process for generating the complete finite element computer program is described in Chapter II, Section 2.1.

The finite element computer program utilized in this study is the latest NASA STRUCTURAL ANALYSIS (NASTRAN) version - level 15.5.1. Structural elements are provided for specific representation of more common types of construction including rods, beams, shear panels, and plates. The range of analyses that can be solved include static, elastic stability, and dynamic structural problems.

NASTRAN has been specifically designed to treat large problems with many degrees of freedom. Computation procedures in NASTRAN were selected to provide the maximum obtainable efficiency for large problems. NASTRAN uses a finite element model, wherein the distributed physical properties of a structure are represented by the elements interconnecting at the grid points. Loads are applied

either at grid points or on the elements for which displacements are calculated. (30)

The system displacements {u} in Equations (1), (3), (5), and (6) locate individual grid or node points which schematically represent the structure. The structure is approximated by connecting these grid points with the proper elements (rods, bars, beams, and plates) which best describe the individual shapes and the overall configuration to be In the process of connecting the elements to analyzed. the grids, material and geometrical properties (areas, moments of inertia, modulus of elasticity, Poisson's ratio) for each element can be identified. By organizing all of the grids, elements, and properties in the form acceptable to NASTRAN, or other general purpose finite element computer programs, the stiffness matrix [K] in Equations (1), (2), (4) and (6) can be generated in the computation process. The loads {F} that apply to each element and/or discrete grid points can be identified, and the cards generated.

Triangular and quadrilateral elements with both inplane and bending stiffness are used in this study. The NASTRAN (level 15) numerical results were calculated using Langley Research Center's CDC-6000 series computers. Also, HP-9810 programmable desk top calculator was used to assist in interpreting the data and to automate the empirical formula

developed. The approximate number of degrees of freedom required to model the different configurations in this study are as follows: shell, 1500; pipe, 300; and pad, 300. Once the displacements {u}, Equation (6), are determined, internal element stresses are obtained. Finally, inside and outside surface stresses for each element in the structure are computed by NASTRAN from these internal stresses (membrane stress + bending stress). A shell, pipe, and two pad configuration (modeled with 2400 degrees of freedom) is presented in Appendix A.

with regard to the cost of preparing the finite element program input data previously described, it is quite likely that this will exceed the cost of the computer operation in most cases. In any numerical computer method, the characterization process of a structure can be tedious and time-consuming. A major part of the cost of data preparation is spent in eliminating errors in the extensive tables of numbers required to describe the idealization. The extent of the input process can only be minimized by the use of automation. In order that the finite element method may be used effectively as a research, analysis, or design tool, it is essential that automatic mesh generation programs be developed which will define the idealizations of arbitrary shell geometries. Of similar importance to the practical use of such programs is automatic plotting

to present the configuration and results in a readily usable format.

A computer program to "automatically" punch input cards in the format acceptable to NASTRAN was developed. This program generates the input for shell, pipe, and pads: grid, element, load, compatibility, and boundary condition cards. The cards punched from this program are input to NASTRAN for solving the inside and outside surface element stresses. Many configurations were solved (presented in Chapter V) in order to obtain trend data and comparative results. As a spin-off of the NASTRAN program, plots can be obtained for pictorial or presentation purposes and as a debugging tool. Sample plots are shown in Figures 2.4.1, 2.4.2, and 2.4.3.

CHAPTER III

ACCURACY STUDY

3.1 Introduction

In the finite element analysis of any structure, a first requirement is the idealization of the structure. For example, a shell surface (shown in Figure 3.1.1) is divided into a system of appropriately shaped pieces. The individual pieces must be standardized as simple shapes such as triangles, rectangles, or quadrilaterals in order that their stiffness properties may be defined. This requirement imposes a certain degree of approximation in idealizing the geometry of shells: a curved boundary will usually be represented as a series of straight line segments. In general, this boundary approximation is not severe, and it can be reduced to any desired error limit by reducing the size of the elements.

The most important approximation is in the shell behavior assumption itself. If the shell is treated as a two-dimensional surface rather than as a three-dimensional solid, this implies certain assumptions and limitations. For example, in the Kirchhoff theory, it is assumed that stresses in the direction normal to the shell surface are small compared to membrane stresses, and lines normal to the surface are assumed to remain normal and unstrained

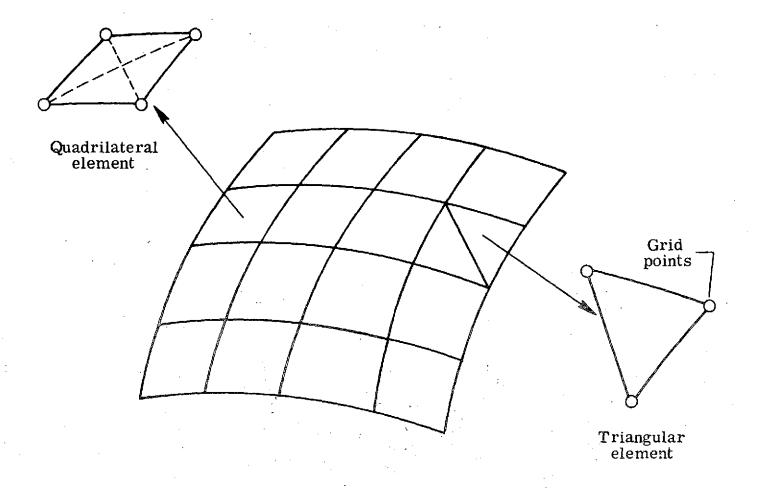

Figure 3.1.1.- Discretized shell.

during deformation. Approximations of this type are not a special feature of the finite element solution but are inherent in any shell theory. Another common approximation, in addition to the straight line segment representation of boundaries, is that the elements connecting grid points are flat surfaces or a group of several flat surfaces. The great advantage of this assumption is that the membrane and bending stiffness properties of the individual flat plates are uncoupled. The coupling, which is characteristic of shell behavior, is developed only in the assemblage of the flat plates into an approximation of the curved shell surface. (31)

3.2 Types of Finite Elements

The nature of the finite element approximation is such that the analytical results generally converge toward the true solution as the finite element mesh size is refined. Other factors in the convergence criteria are the number of grid points specified for each element, type of elements, and primarily, the number of degrees of freedom (DOF) at each grid. The Kirchhoff theory takes account of five DOF (3 translations and 2 rotations about axes tangent to the shell surface). Most shell elements make use of these same 5 DOF at each grid.

The finite elements employed in the discretized shell

in Figure 3.1.1 are both planar triangles and quadrilaterals assembled from 4 planar triangles. The forces and stresses on these elements are shown in Figure 3.2.1(30)brane stiffness of the triangular element is represented by the well-known constant strain triangle and shown in Figure 3.2.2. The components of displacement, u and v, are parallel to the local coordinate system (element X and Y axes). The bending property based on cubic displacement patterns is given by a fully compatible plate bending element, a Clough bending triangle. (32) This triangle is formed by subdividing it into three basic bending triangles as shown in Figure 3.2.3. The X-axis of each sub-triangle corresponds with an exterior edge, so that continuity of slope and deflection with surrounding Clough triangles is assured. The added grid point in the center is like the other grid points in that equilibrium of forces and compatibility of displacements are required at the center point. tion, the rotations parallel to the internal boundaries at their midpoints, points 5, 6 and 7, are constrained to be continuous across the boundaries. The equations for slopes in the basic triangles contain quadratic and lower order terms, and since the normal slopes along interior boundaries are constrained to be equal at three points (both ends and the middle), it follows that slope continuity is satisfied along the whole boundary. Displacement continuity on all

Structural modeling

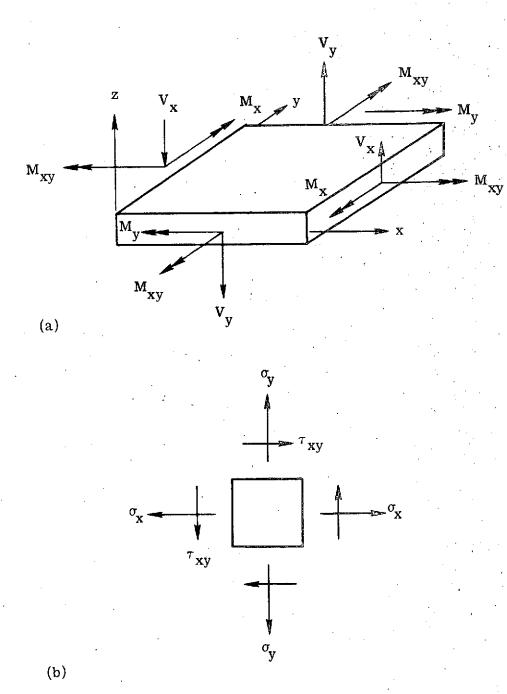

Figure 3.2.1.- Forces and stresses in plate elements.

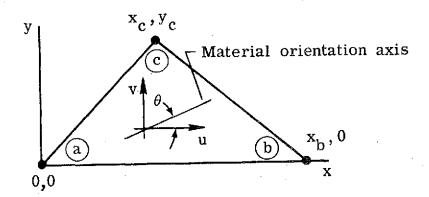

Figure 3.2.2.- Triangular membrane element.

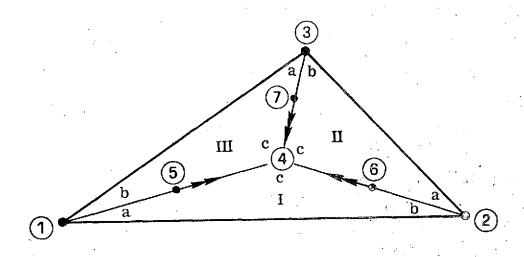

Figure 3.2.3.- Clough bending triangle.

boundaries is automatically satisfied when the displacement function contains only cubic and lower order terms. Thus, complete continuity of slope and displacement on all interior and exterior boundaries is assured for the Clough triangle.

The Clough triangle is superimposed with a membrane triangle to form triangular elements with both membrane and bending stiffness. Therefore, this triangular element has 5 DOF at each corner, 2 deriving from membrane displacements and 3 from the bending. The quadrilateral plate was developed to provide improved membrane strain behavior while retaining the basic 5 DOF per grid system. It is formed as 4 planar triangles as shown in Figure 3.2.4 plus 3.2.5, with the grids modeling the shell midsurface. Each triangle has one-half of the bending, stiffness or one-half of the thickness (membrane) assigned to the quadrilateral element. Since four points, in general, do not lie in a plane, care must be taken to ensure equilibrium and compatibility. Rather than try to define a warped surface, an averaging process is used on the noncoplanar membrane triangles. The bending element uses two sets of overlapping basic bending triangles. Since coupling between membrane stiffness and bending stiffness is not, at present, included in NASTRAN, quadrilateral elements with both membrane and bending properties are treated by simple superposition of their

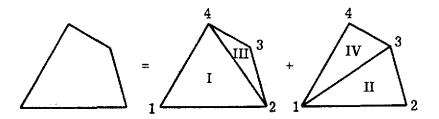

Figure 3.2.4.- Quadrilateral membrane element.

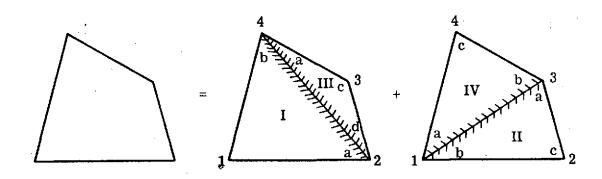

Figure 3.2.5.- Quadrilateral bending element.

membrane and bending stiffness matrices. The following NASTRAN elements are the ones used in this research:

- 1. TRIA 2 The triangular element with both inplane and bending stiffness.
- 2. QUAD 2 A quadrilateral element similar to TRIA 2.

3.3 Shell

In this section, consideration is given to the accuracy obtained with different mesh sizes and the two types of elements (TRIA 2 and QUAD 2) used to obtain the peak stress concentration factor for a pressurized cylindrical shell with a circular hole, Figure 2.2.1. A quarter of the shell is chosen as the model: shell radius, R; length, \geq 2R; and the hole radius, ρ_{a} . A typical finite element model is shown in Figure 3.3.1. If the element size or general mesh geometry is too large at discontinuities (such as a penetration), the structure will be "too stiff". finite element approximations to peak stress concentration factors will be below the correct answer. This model provides a gradual transition of large to small elements as the hole opening is approached. Since the "radial" section is the easiest to generate or modify, different mesh arrangements and elements will be used to compare the accuracy of peak stress concentration factors (SCF) to "exact" solutions.

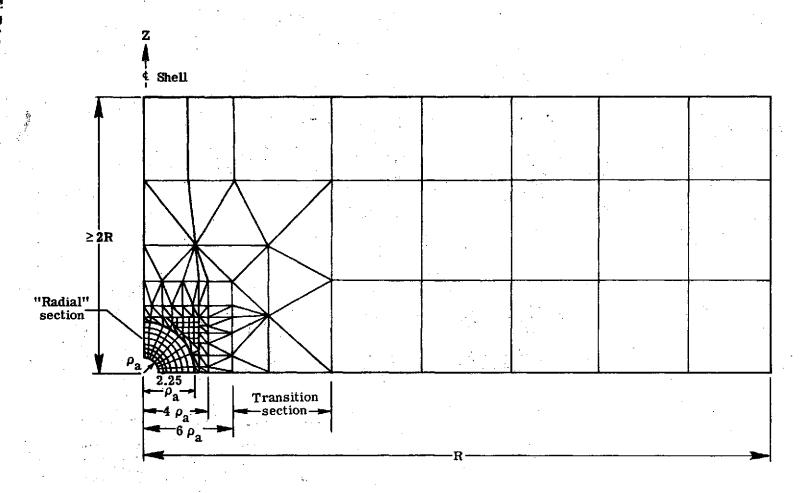

Figure 3.3.1.- Typical plan view of a finite element model of a cylindrical shell with a circular hole.

The rectangular arrangement of quadrilateral (RQ) elements of the "radial" section is shown to a larger scale in Figure 3.3.2. The right (RDT) and left (LDT) diagonal arrangements of triangular elements for the "radial" section are shown in Figures 3.3.3 and 3.3.4, respectively. refined version (additional grid points) of left diagonal triangular (RLDT) elements is shown in Figure 3.3.5. triangularizing of only the first element in the rectangular arrangement of quadrilateral (1TRQ) elements is shown in Figure 3.3.6. These code names for identifying the articulation arrangements are similar to those used by Melosh. (31) It should be noted that efforts were pursued in refining these configurations by grouping the same number of grid points very near the hole (see Figure 3.3.7) - all to no avail. Also, results for refining of the RLDT, regardless of the local transition, were in error. This idea of too much local refining is known. (31) When the elements were smaller than one-half of the shell thickness, the peak SCF oscillated about the "exact" solution.

A summary of the computer runs for peak stress concentration factors for a pressurized cylindrical shell with force around the hole is presented in Table 3.3.1. The units used in this table and throughout this study are in the English or American System (inches and pounds). The RQ radial section model approximates the peak inside SCF

to within -11% (below) of the theoretical or "exact" solution obtained in Reference (3). The approximations for the triangular arrangements (RDT, 1TRQ, LDT) are converging to the theoretical solution without local Many authors have reported the midrefining (RLDT). (1,2,3)surface (average) SCF. Since this is not the peak value, the largest SCF (inside) will be the gauge in the accuracy comparisons to determine the arrangement to use for all other shell/force problems. LDT (which is much easier to generate) peak inside SCF is slightly more accurate (-1.05% difference) than the RLDT (+1.14% difference). Therefore, the LDT arrangement is the one chosen to obtain the peak SCF results for shell configurations with just a force around the hole.

3.4 Shell and Pipe

The next configuration to be considered is two intersecting circular cylinders (shell and pipe) as shown in Figure 2.2.3. The same shell models in Section 3.3 are used; therefore, a quarter of the pipe is modeled: hole radius, ρ_a ; pipe radius, ρ_o ; pipe thickness, t; pipe length, $\geq 2 \rho_a$, and all of the shell parameters previously described. Typical finite element models for a pipe are arranged and shown as follows: rectangular quadrilateral (RQ), Figure 3.4.1; right diagonal triangles (RDT), Figure 3.4.2; and left diagonal triangles (LDT), Figure 3.4.3. The successful implementation of the compatibility equations for the pipe/shell juncture was accomplished by using the following:

- 1. The θ relationship in Equations (8) and <u>not</u> $\theta = 2 \text{ Arc sin } (\frac{\rho \sin \phi}{2R}) \text{ or } \theta = 2 \text{ Arc sin } (\frac{\rho_0 \sin \phi}{2R}),$
- 2. The same coordinate system for both the shell and the pipe, and
- 3. The same coordinate system for input, solution, and output.

A summary of the peak SCF computer solutions for shell and pipe is presented in Table 3.4.1. The finite element

approximations are converging to the theoretical solutions. $^{(1,3)}$ For T=1.084, the convergence is as good as the shell problem. For the same reasons, the left diagonal triangular shell and the right diagonal pipe is the configuration used in the numerical NASTRAN results. For comparison purposes, computer results for two other shell thicknesses (T=1.25 and 2.167) for the "simplest" and the chosen configurations are also shown.

Figures 3.4.4 through 3.4.7 show the comparison of the NASTRAN results with experimental and analytical data. The difference between the chosen NASTRAN configuration and the experimental data from that in Cranch (14) is only 8.38%, see Figure 3.4.4. Another example of trend and accuracy is the nozzle-to-cylinder intersection model in Figure 3.4.5. The analysis was performed by Prince and the experimental investigation by the Oak Ridge National Laboratory. (7) Remarkable accuracy is achieved (-3.95% difference) with a direct trend comparison, see Figures 3.4.6 and 3.4.7. Other examples of experimental data and numerical/analytical findings are presented in the results, Chapter V.

3.5 Shell, Pipe, and Pad

The preceding sections provided comparisons of the accuracy of a variety of finite element solutions to theoretical, numerical, and experimental results. Results for this specific case (shell, pipe, and pad) are limited; however, a configuration was chosen to test the MPC cards. This configuration is two intersecting circular cylinders reinforced with a pad. The same shell and pipe models in Sections 3.3 and 3.4 are used; consequently, a quarter of the pad is modeled: outside pad radius, $\rho_{\rm p}$; and pad thickness, $t_{\rm p}$; and all of the shell and pad parameters previously described. Typical finite element models for a pad are similar to those of the shell "radial" section, see Figures 3.5.1 through 3.5.3. A summary of the peak SCF computer solutions for a shell/pipe/pad configuration is presented in Table 3.5.1.

There have been six shell/pipe/pad configurations experimentally investigated. (14,15,17,22,24) The NASTRAN result as compared to first set of data (14) is shown in Figure 3.5.4. The dashed line is the author's extension of the available experimental curve. The descriptions of the two models to show convergence is presented in Table 3.5.2. The second comparison (15) is shown in Figure 3.5.5 and presented in Table 3.5.3. This trend comparison is outstanding. The accuracies of the two, -3.85% and -4.42%,

is remarkable. The convergence of these NASTRAN models for the two experimental cases lends authenticity to the first numerical case for which there is no comparison. Therefore, the LDT shell, RDT pipe, and LDT pad will be used as the finite element model for other numerical NASTRAN results. The other four experimental results will be presented in Chapter V (for comparison to the formula developed in Chapter IV).

3.6 Shell, Pipe, and Pads

The shell, pipe, and pads configuration is often used in the design and construction of pressure vessels. One experimental investigation for this configuration was located through a paper by Kitching and Perkins. (23) experimental results were for two intersecting circular. cylinders (pipe and shell) reinforced with two pads (inside and outside of the shell) as shown in Figure 3.6.1. experimental result was obtained during an investigation by the British Welding Research Association (BWRA). (24) The same shell, pipe, and pad models in previous sections are used; moreover, a quarter of the second pad is modeled identical to Figures 3.5.1 and 3.5.3. A summary of the peak SCF computer solutions, for the simplest and most accurate type (from previous sections) finite element configurations, is shown in Table 3.6.1. This is the only shell/pipe/pads experimental or numerical result available and the LDT type model has a difference of 9% above the exact answer. "However, the actual maximum value (SCF) would be slightly higher than the one measured in the test since it is impossible to measure immediately at a point of discontinuity." (23) The discontinuity point would be at the NASTRAN peak SCF location - inside shell surface at The difference would be < 9%, which is within $\phi = 0$ and ρ_a .

engineering requirements. Therefore, the LDT shell, RDT pipe, and LDT pad(s) will be used in modeling all other numerical NASTRAN results.

CHAPTER IV

FORMULA .

4.1 Introduction

In practical applications one frequently encounters problems in which a circular cylindrical shell is submitted to the action of forces distributed symmetrically with respect to the axis of the cylinder. The stress distribution in wind tunnels, cylindrical containers, and circular pipes under uniform internal pressure are examples of such problems. (34)

For the case of circular cylindrical shells arbitrarily loaded, two first approximation theories are of prime importance - (1) Love's first approximation theory and (2) its simplified version due to Donnell. The simplified version led to three partial differential equations in three displacement components. These three equations contain terms which higher approximation theories have shown to be negligible. It is therefore permissible to simplify the equations by omitting such terms. (9) If these terms are omitted (only pressure is considered) and the thickness of the shell is constant, these Donnell equations lead to a single fourth order equation in w, the radial deflection, for the case of axisymmetrically loaded circular cylindrical shells. This equation obtained by a number of authors (9,34-36) is

$$\frac{d^{4}w}{dz^{4}} + \frac{ETw}{R^{2}D} = \frac{D}{D}$$
 (13)

with

$$D = \frac{ET^3}{12(1 - v^2)}$$

where

w is the radial deflection

E is Young's Modulus of the shell

R is the shell mid radius

T is the shell thickness

p is the internal pressure

v is the Poisson's ratio of the shell.

For the case of unsymmetrically loaded circular cylinders, the linear shallow, thin shell equations may be readily combined into two differential equations involving only the membrane stress function F and the normal displacement w. The compatibility and equilibrium equations are

$$\nabla^{4} F = \frac{ET}{R} \frac{\partial^{2} w}{\partial z^{2}}$$

(14)

$$\nabla^{\mu}_{W} + \frac{1}{RD} \frac{\partial F}{\partial z^{2}} = \frac{p}{D}$$

where
$$\nabla^4 = \frac{\partial}{\partial z^4} + \frac{2\partial}{\partial z^2 \partial y^2} + \frac{\partial}{\partial y^4}$$

Elimination of the function F between the two equations above yields an eighth order partial differential equation in w of the form

$$\nabla^8 w + \frac{Et}{DR^2} \frac{\partial^4 w}{\partial Z^4} = \frac{p}{D}$$
 (15a)

or

$$\nabla^{8}_{W} + 64\beta^{4} \frac{\partial^{4}_{W}}{\partial z^{4}} = \frac{p}{D}$$
 (15b)

where

$$\beta^4 = \frac{ET}{16R^2D} = \frac{3(1 - v^2)}{16R^2T^2}$$

Equations (15) are known as Donnell's linear theory. (1-3, 9-11)
4.2 Force Around Hole

The result of a perturbation solution to Equation (15b), modified to include a circular hole covered by a membrane (Figure 4.2.1), through terms of order $(\beta \rho_a)^2$ is a stress concentration factor at the hole-shell boundary. (2)

SCF =
$$\frac{3}{2}$$
 + cos 2 ϕ + $\pi(\beta \rho_a)^2 (1 + \frac{5}{4} \cos 2 \phi) + . . . (16)$

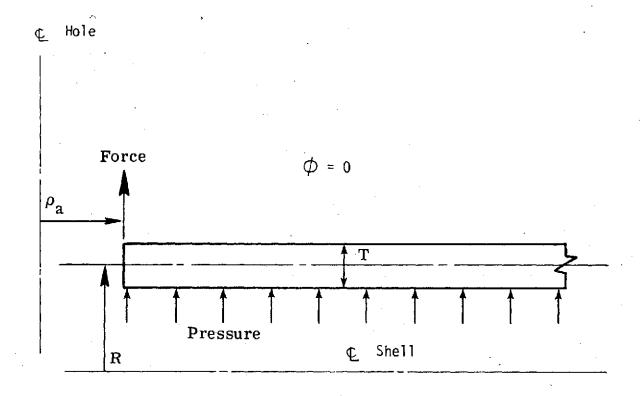

Figure 4.2.1.- Penetration (radius ρ_a) in a pressurized cylindrical shell (mid radius R, thickness T, and Poisson's ratio ν) covered by a membrane.

For the case of $\phi = 0$, Equation (16) becomes

SCF =
$$2.5 + \frac{9}{4} \pi (\beta \rho_a)^2$$
 (17)

where ρ_a is the hole radius.

Savin's formula (4) for the same problem is

$$SCF = 2.5 + \frac{2.3}{RT} \rho_a^2 \qquad . \tag{18}$$

Lind's equation (26) is

SCF = 1 + 4
$$\beta \rho_a \left(1 + \frac{T}{2R}\right)$$
 (19)

 $Mershon^{(27)}$ obtained for the same problem but with a pipe intersecting the shell hole

SCF = 2.5 +
$$\frac{\rho_o}{R}$$
 $(\frac{2R}{T})^{1/2}$ = 2.5 + $(\frac{2}{RT})^{1/2}$ ρ_o (20)

where ρ_0 is the pipe mid radius.

Mershon's Equation (20) is restricted to $t/T \stackrel{\sim}{\sim} 0$ (force around hole only) or t/T small - where t is pipe thickness.

For v = 0.3, these Equations (16 through 20) reduce to

$$SCF_{Van Dyke} = 2.5 + \frac{2.92 \rho_a^2}{RT}$$
 (21a)

$$SCF_{Savin} = 2.5 + 2.3 \frac{\rho_a^2}{RT}$$
 (21b)

$$SCF_{Lind} = 1 + 2.585 \frac{\rho_a}{(RT)^{1/2}}$$
 (21c)

$$SCF_{Mershon} = 2.5 + 1.414 \rho_{o}$$
 (21d)

The first attempt at a rational analysis of a long pressurized cylindrical shell having a small circular hole and closed at its ends is due to Lur'e. (6) Due to errors introduced in the boundary conditions, his results are incorrect. The terms in Equation (16) of order $(\beta \rho_a)^2$ were one-half the values obtained originally by Lur'e. This error was also confirmed by Eringen (8) and Lekkerkerker (1). Eringen, Naghdi, and Thiel (3) presented a study using the exact solution of partial differential equations of thin, shallow, cylindrical shell theory. The boundary conditions were satisfied by use of Fourier series and the least square error technique through the aid of extensive numerical calculations of the force only around a circular hole in a cylindrical shell. A comparison of the results from this "exact" approach with Equation (21) is shown in Figure 4.2.2.

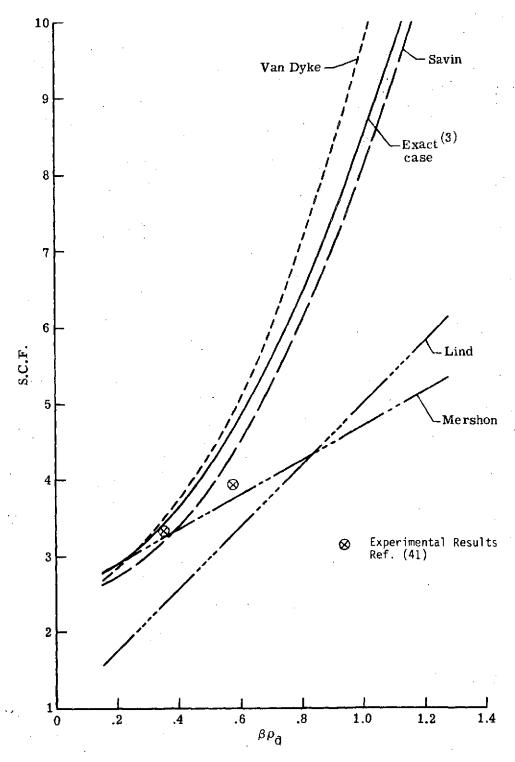

Figure 4.2.2.- Comparison of formulas with exact results.

The two experimental results are those of Houghtan and Rothwell. (41) In both of these experiments, only the membrane stresses were measured. The stress concentration factors correspond to the ratio of the maximum membrane stress at the hole to the membrane stress in the shell far from the hole. Excellent agreement is shown for the first data point ($\beta\rho_a=0.35$). The experimental membrane covering the hole consisted of a very flexible, thin metal plug. This may have introduced slight restraints on the freedom of the hole edge. By measuring only the membrane stress and, perhaps, introducing the slight restraint, the peak SCF for the second experiment would be higher due to the larger size hole ($\beta\rho_a=0.58$).

The Van Dyke Equation (21a) is the only conservative equation in comparison with the "exact" results $^{(3)}$ and the first experimental case. Van Dyke's starting series for small $\beta\rho_a$, given by Equation (16), is generally accurate to a $\beta\rho_a$ of about 0.3. $^{(2)}$ The required engineering accuracy is exceeded for $\beta\rho_a > 0.6$; therefore, this equation is the one chosen to improve on in the following format for the force around the hole

$$SCF_{Force} = 2.5 + \lambda \frac{\rho_a^2}{RT}$$
 (22)

0

where 2.5 is the stress concentration factor for a flat plate weakened by a circular hole with the plate stretched per unit length in one direction and with one-half of this stretch per unit length in the other direction,

and

 $\frac{\rho_a}{RT}$ is a function to increase the stress due to shell curvature and thickness, and hole size,

with λ for values of $\frac{\rho_a}{(RT)^{1/2}}$ shown in Figure 4.2.3.

The values of λ to go in Equation (22) can be taken from this curve (Figure 4.2.3) or the maximum value of λ = 2.7 could be used. This value is used in Equation (22) in this report. For ν = 0.3 the result is

SCF Force = 2.5 + 2.7
$$\frac{\rho_a^2}{RT}$$
 (23a)

or for any v

SCF Force = 2.5 + 6.537
$$(\beta \rho_a)^2$$
 (23b)

where
$$\beta \rho_a = \frac{(3(1-v^2))^{1/4}}{2} \frac{\rho_a}{(RT)^{1/2}}$$

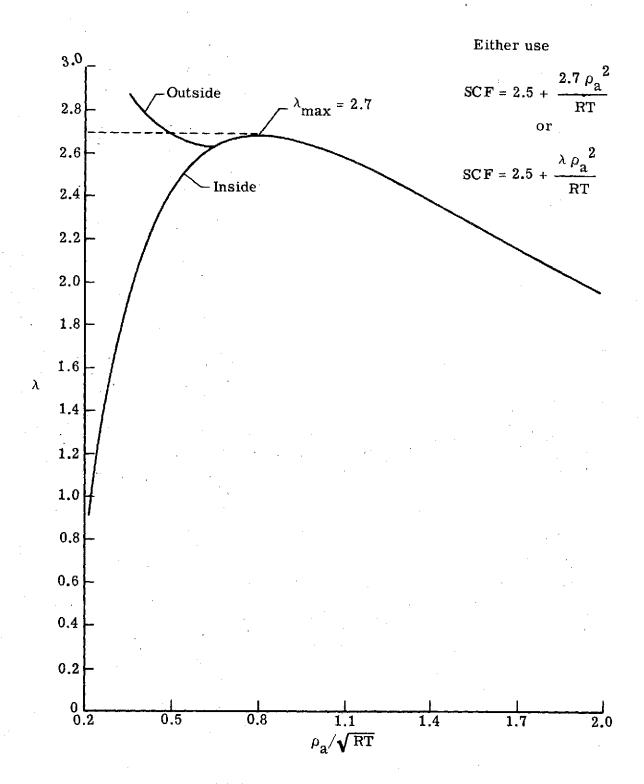

Figure 4.2.3.- Values of λ in shell with force equation.

4.3 Pipe Around Hole

The installation (physically or analytically) of a pipe into a cylindrical shell (Figure 4.3.1) reduces the peak stress concentration factor at the shell-pipe juncture. A function or reduction factor is needed to decrease this stress due to a small amount of reinforcement from the pipe. The reduction is dependent on the amount of pipe reinforcement (opening and pipe thickness) not needed to withstand the pressure. Thus, the following form is assumed

$$SCF_{Pipe} = SCF_{Force}$$
 (reduction factor). (24)

The usual pressurization of cylindrical vessels (wind tunnels) is analogous to a suddenly applied load. (37) The dynamic response of a structure due to this type load is a dynamic load factor of "one minus some term." Therefore, the above reduction factor takes the form

$$1 - (\beta \rho_0)^2$$
 (pipe to shell thickness ratio) (25)

where ρ_0 is mid surface radius of the pipe and β is modified to include Poisson's ratio of the pipe. The pipe to shell thickness ratio (to be of the same order as β) will be taken as $(t/T)^{1/4}$. Equation (24) becomes

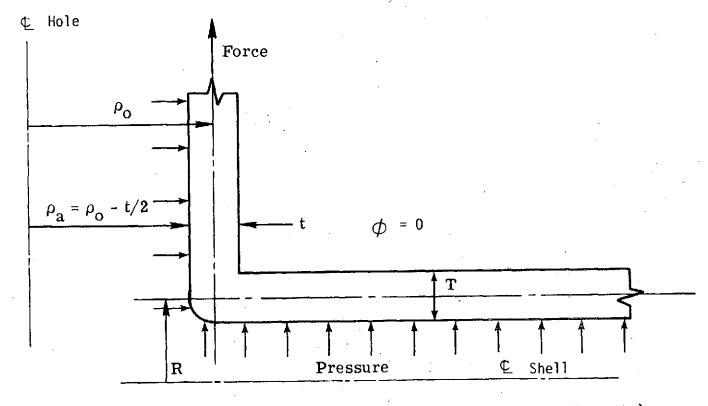

Figure 4.3.1.- Pipe (mid radius ρ_0 , thickness t, and Poission's ratio ν_p) in a pressurized cylindrical shell (mid radius R, thickness $\mathbf T$ and Poission's ratio ν).

SCF pipe = SCF force
$$|1 - (\beta_1 \rho_0)^2 (\frac{t}{T})^{1/4}|$$
 . (26)

The total equation (23 and 26) developed thus far is

SCF pipe =
$$(2.5 + 6.537 (\beta \rho_a)^2) |1 - (\beta_1 \rho_o)^2 (\frac{t}{T})^{1/4}|$$
 (27)

4.4 Pipe and Reinforcing Pad Around Hole

The addition of an inner or outer reinforcing pad to a pipe in a cylindrical shell is shown in Figure 4.4.1. The two new parameters introduced with this configuration are the outside radius (ρ_p) and the thickness (t_p) of the inner or outer pad. The major parameters from Equation (27) that contribute to this configuration's influence on the SCF are the mid radius (R), the thickness (T) of the shell and the inside radius (ρ_a) , the thickness (t) of the pipe. Thus, a function to decrease the stress due to a reinforcing pad around the pipe or hole should contain ρ_p , R, ρ_a , t_p , and t or T. This function should be similar to $\beta \rho$ and multiplied times a pad to shell or pipe thickness ratio to some power. Note that

$$\beta \rho = \frac{(3(1-v^2))^{1/4}}{2} \frac{\rho}{(RT)^{1/2}} \propto \frac{\rho_p}{(R\rho_a)^{1/2}}.$$
 (28)

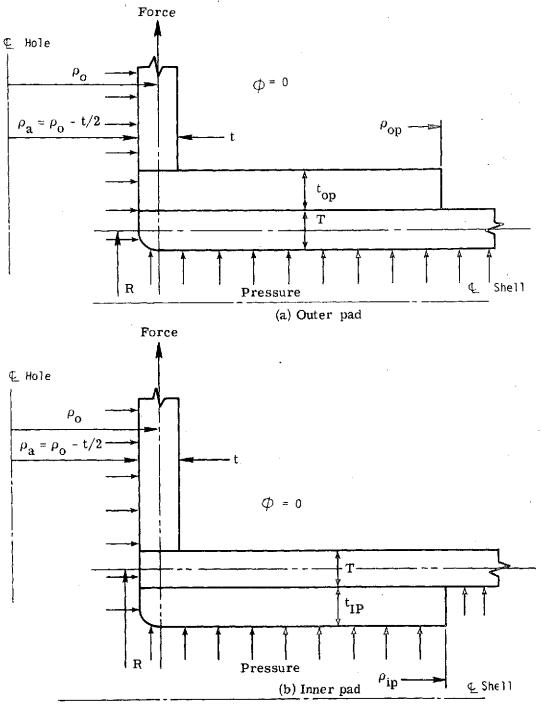

Figure 4.4.1.- Pipe (mid radius $\rho_{\rm o}$, thickness t, and Poisson's ratio $\nu_{\rm p}$) in a pressurized cylindrical shell (mid radius R, thickness T and Poisson's ratio ν) reinforced with an inner or outer pad (outside radius $\rho_{\rm p}$ and thickness $t_{\rm p}$).

The pad to shell or pipe thickness ratio (to be of the same order as β) will be taken as $(t_p/TH)^{1/4}$.

Therefore, the reduction in peak stress concentration factor due to an inner or outer reinforcing pad to a pipe in a cylindrical shell is

$$\frac{\rho_{\mathbf{p}}}{(\mathbf{R} \rho_{\mathbf{a}})^{1/2}} \qquad (\frac{\mathbf{t}}{\mathbf{TH}})^{1/4} \tag{29}$$

The limits as to when each thickness should be used (TH=t for $\frac{R}{T} > 33$ and TH=T for $\frac{R}{T} \leqslant 33$) are discussed in Chapters V and VI under the presentation and discussion of results. The SCF equation becomes

SCF pad = SCF pipe -
$$\frac{\rho_{p}}{(R \rho a)} 1/2 \left(\frac{t_{p}}{TH}\right)^{1/4}$$
 (30)

The total equation (27 and 30) developed thus far is

$$SCF_{pad}^{\rho} = (2.5 + 6.537(\beta \rho_a)^2)|1 - (\beta_1 \rho_o)^2 (\frac{t}{T})^{1/4}|$$

$$- \frac{\rho_p}{(R \rho_a)} 1/2 (\frac{t_p}{TH})^{1/4}$$
(31)

where $ho_{
m p}$ is outer or inner outside pad radius and $^{
m t}_{
m p}$ is outer or inner pad thickness.

4.5 Pipe and Reinforcing Pads Around Hole

The addition of inner and outer reinforcing pads to a pipe in a cylindrical shell is shown in Figure 4.5.1. The only new parameters introduced with this configuration are the outside radius and thickness of the second reinforcing pad. Therefore, the same type of term as Equation (29) will apply as a reduction to Equation (31) to obtain the peak stress concentration factor for two pads. The general SCF equation becomes

SCF =
$$(2.5 + 6.537(\beta \rho_a)^2)|1 - (\beta_1 \rho_o)^2 (\frac{t}{T})^{1/4}|$$

$$- \frac{\rho_{op}}{(R \rho_a)} 1/2 (\frac{t_{op}}{TH})^{1/4} - \frac{\rho_{ip}}{(R \rho_a)} 1/2 (\frac{t_{ip}}{TH})^{1/4}$$
(32)

where subscripts o and i are for the outer and inner pads, respectively.

One can obtain the peak SCF for any of the previously developed five cases (force, pipe, outer pad, inner pad, and outer and inner pads) by merely substituting the appropriate parameters in Equation (32). For example, the pipe problem would be solved with $\rho_{\rm op} = \rho_{\rm ip} = t_{\rm op} = t_{\rm ip} = 0$, which would result in Equation (27). The practical approach

140

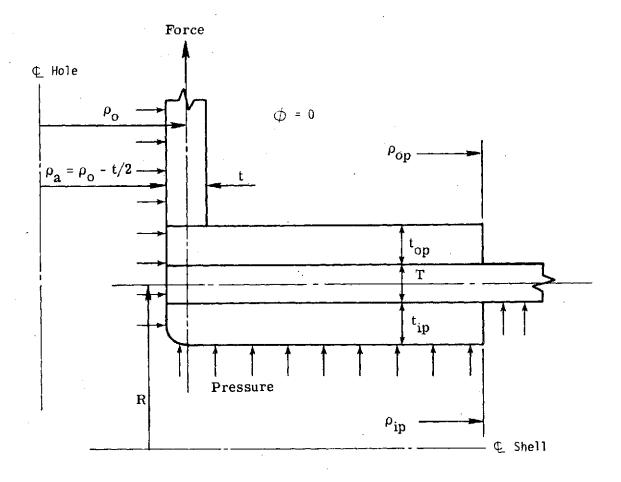

Figure 4.5.1.- Pipe and shell reinforced with inner and outer pads.

in the construction of cylindrical shells is to generally reinforce around pipes; therefore, these five configurations are the major thrust of this research. Another combination of cases can be addressed, i.e. force (t = 0) and pad(s). The physical significance of force, no pipe, and pad(s) could be (1) a cap welded to a reinforcing pad to close off an opening and (2) glass ports for observing the inside of cylindrical pressure vessels (test sections).

The accuracy of the formula is determined by comparing to available and applicable published numerical, theoretical, and experimental data and to the analytical (NASTRAN) results. Many different cases and examples of this formula were pursued in order to uncover the restrictions in the formula. The accuracy, results, and applications are presented and discussed in Chapters V and VI.

Since the formula is compared to theoretical (Shell theory) and to the author's computer (NASTRAN) results, the reliability of the answers from shell theory and NASTRAN in this study is needed. An analogy to the cylindrical shell problem is the example of pure bending of an infinite plate with a circular hole. Reissner (42) addresses this problem by including the effect of transverse shear deformations. It is assumed in Shell theory and NASTRAN that the stresses vary linearly across the thickness. Reissner obtained a factor 6/5 (in lieu of 1.0) in front of the transverse

shear deformation terms in the stress-strain equations for two-dimensional plate theory. The significance of this difference is presented by comparing to an exact (three-dimensional elasticity theory) analysis of the plate with a circular hole subject to pure bending. The effect of transverse shear on the peak stress concentration factor is negligible provided $\rho_{\rm a}/{\rm T}$ is greater than about 3.0. Therefore, even though Reissner's paper is concerned with a flat plate, the effect of transverse shear on this study will be negligible as long as $\rho_{\rm a}/{\rm T} > 3.0$ and ${\rm R}/{\rm T} > 25.0$.

It is permitted in NASTRAN to use any shear factor in front of the transverse shear deformation terms. (43,44) The factor used in this study is 1.0. Therefore, a slightly different SCF than the exact answer will be obtained. All of the theoretical and NASTRAN results presented in this study have a ρ_a/T ratio greater than 4.0, except the NASTRAN configurations where the shell thickness equals 8.96 (ρ_a/T = 1.2 and R/T = 13). It will be shown in Chapter V that for experimental results for $\rho_a/T < 0.6$ and R/T < 15, the transverse shear effects are not negligible.

ORIGINAL PAGE IS OF POOR QUALITY

CHAPTER V

PRESENTATION OF NUMERICAL RESULTS

5.1 Introduction

The finite element technique described in Section 2.1 has been used to complete numerical analyses for the configurations previously described (Section 2.2, Chapters III and IV): shell with force around hole, shell and pipe, and shell/pipe/pad(s). The units used throughout this study are in the English or American System (inches and pounds). Except where noted in these results, Poisson's ratio is taken as 0.3 and Young's modulus as 29 x 10⁶ psi. The membrane stress of a cylindrical shell is well known.

$$\sigma_{\rm m} = P \frac{R}{T} \tag{33}$$

The ratio of the largest principal stress at a point in question to that which would occur at that point if the shell were not penetrated will be called a stress concentration factor (SCF). This is defined by

$$SCF = \frac{Max. stress}{\sigma_{m}}$$
 (34)

where σ_{m} is defined by Equation (33).

The numerical (NASTRAN) results were calculated using Langley Research Center's CDC-6000 series computers. All of the NASTRAN models are composed of triangular and quadrilateral elements with both inplane and bending stiffness. The pressurized cylindrical shell with a circular penetration is modeled as follows:

- 1. General shell, Figure 3.3.1
- 2. Radial shell section, Figure 3.3.4
- 3. Pipe, Figure 3.4.2
- 4. Pad(s), Figure 3.5.3.

For all of the tabulated results, the peak SCF at the shell/hole or pipe/pad(s) juncture is given. Appendix A contains a representative NASTRAN run. The detail computer printouts of the numerous cases fill a volume of 7 cubic feet; therefore, for brevity, Appendix B contains typical one page summaries of the NASTRAN runs presented in this section and Chapter III. These summaries for shell thicknesses 0.896 and 2.215 are organized in the following configurations: force, pipe, pipe and pad, pipe and pads, force and pad, and force and pads.

The one page summary defines parameters used to model that configuration: shell mid radius (R) and thickness (T); hole radius (ρ_a); pipe mid radius (ρ_o) and thickness (t); outer pad outside radius (ρ_{op}) and thickness (t_{op}); inner pad outside radius (ρ_{ip}) and thickness (t_{ip}); and Poisson's

radio of shell (v), pipe (ν_p), and pad(s) (ν_{PAD}). The location of each SCF is determined by (1) the angle (ϕ , see Figures 2.2.1 and 2.2.2); (2) inside surface (I/s) or outside surface (0/s) of shell, pipe, and pad(s); and (3) ratio of the grid point location (ρ , see Figures 2.2.1 and 2.2.2) divided by the pipe mid radius (ρ_o). The peak SCF used as the design criterion is the largest of all SCF values computed for a configuration.

The accuracy of the NASTRAN results is determined by comparing to theoretical and experimental data. Since limited data are available for reinforced penetrations, many different configurations were modeled to supplement the published "exact" data to provide the accuracy and restrictions to the formula.

5.2 Formula Restrictions and Conditions

The accuracy of the formula presented in Chapter IV was improved by imposing certain restrictions and conditions based on the results in this chapter. These results were from experimental, theoretical, published numerical, and the NASTRAN analytical results. The general restrictions inherent in any shell theory or finite element solution are as follows:

1.
$$\frac{\rho_0}{R} \leq \frac{1}{2}$$
 (Equation (9))

2.
$$\frac{\rho_0}{t} > 10$$

3. $\frac{R}{T} > 10$ (thin shell theory)

4. $\rho_a/T \ge 1.2$ (Transverse shear effect).

There are other conditions that the author has used to improve the accuracy of the formula. These conditions are

- 1. $\frac{t}{T}$ < 0.4; use SCF = SCF force but retain the calculated SCF pipe for SCF pad(s).
- 2. TH = $\begin{cases} t & \text{for } \frac{R}{T} > 33 \\ T & \text{for } \frac{R}{T} \le 33 \end{cases}$ in Equation (32).
- 3. If ASME "boded" top or bottom pad (39) (approximately Ahole \leq Areinf.), see Figure 5.2.1, and $\frac{\rho_0}{t} > 10$, then treat as a two pad problem with $\frac{1}{2}$ tp on top and $\frac{1}{2}$ tp on bottom.
- 4. $(\beta_1 \rho_0)^2 (\frac{t}{T})^{1/4} \le 1.9$ or pipe is "ill-conditioned."
- 5. If $(\beta_1 \rho_0)^2 (\frac{t}{T})^{1/4} > 1.0$, treat as 'coded' pad condition 3.
- 6. If $0.9 < (\beta_1 \rho_0)^2 (\frac{t}{T})^{1/4} < 1.3$, use $e^{-(\beta_1 \rho_0)^2 (\frac{t}{T})^{1/4}} \text{ in Equation (32) in place}$ of Equation (25).

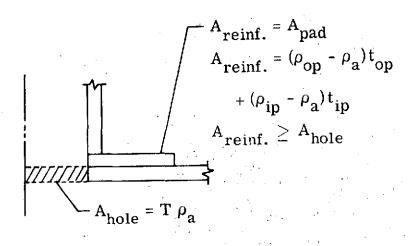

Figure 5.2.1.- Illustration of "reinforcement" required for ASME coded top or bottom pad. (38)

- 7. If t = 0 and configuration is pad(s) reinforced, then $\rho_{\rm p}$ = 2 $\rho_{\rm p}$, TH = T, and treat as "coded" pad.
- 8. SCF from Equations (31) and (32) is always \geq 1.0.

All the formula stress concentration factors are obtained from a computer program which is based on Equation (32) and these restrictions and conditions.

5.3 Force, Pipe, and Pipe/Pad(s)

Several calculations were obtained for the configuration of Figure 4.2.1, force around the hole. These results were computed to compare with theoretical ("exact") results (1,2,3) as well as to provide check points for the formula presented in Chapter IV, Equation (32). Throughout this chapter, the formula answers will be referred to as SCF Ramsey. comparisons between NASTRAN/"exact" (N-E), Ramsey/NASTRAN (R-N), and Ramsey/"exact" (R-E) for different shell and force configurations are presented in Table 5.3.1. second result in this table for $\frac{R}{r} = 156.5$ will arbitrarily be defined as the only membrane result. All other results in this table are in the thin shell theory realm, $\frac{n}{r} > 10$. The overall differences of the comparisons of the results are as follows: N-E, 17.4% and -8.9%; R-N, 8.6% and -12.8%; and R-E, approximately ±5%. The minus sign in this study always indicates less than and the plus sign greater than

the "exact" value. In Figure 5.3.1 all three curves (NASTRAN, "exact" and formula) are approaching the flat plate (β = 0) value at 2.5. For $\beta \rho_a$ < 0.6 the three curves concide. For $\beta \rho_a$ > 0.6 the NASTRAN curve is below (as expected) the "exact", and the formula curve is above (as desired).

The shell and pipe configurations (Figure 4.3.1) are presented in Tables 5.3.2 through 5.3.6 for different types of comparisons for various categories. The types of comparisons are as follows: NASTRAN/exact/Ramsey, Table 5.3.2; analytical/Ramsey, Table 5.3.4; and experimental/Ramsey. Tables 5.3.3, 5.3.5 and 5.3.6. The categories are defined as the following: thin shell, $\frac{R}{T} \geq 10$; and thick shell, $\frac{R}{T}$ < 10; thin pipe, $\frac{\rho_0}{t} \ge 10$; and thick pipe, $\frac{\rho_0}{t}$ < 10. Several NASTRAN thin shell and thin pipe configurations were modeled to compare to theoretical (1,11), numerical (7), and experimental(7,14,17,20,24) results (see Table 5.3.2(a) and 5.3.3(a). The overall differences of the thin shell and pipe NASTRAN results from the "exact" are -14.0% to 8.9%. The formula differences between NASTRAN and "exact" (1,7,11,14,17,20,24) are approximately $\pm 14\%$. Note the configuration where $v_{\rm n}$ = 0.3 and 0.5. The accuracy of the formula as compared to both NASTRAN solutions is approximately 3%.

The thin shell and thick pipe results are shown in Tables 5.3.2(b) and 5.3.3(b). Those in Table 5.3.2(b) are

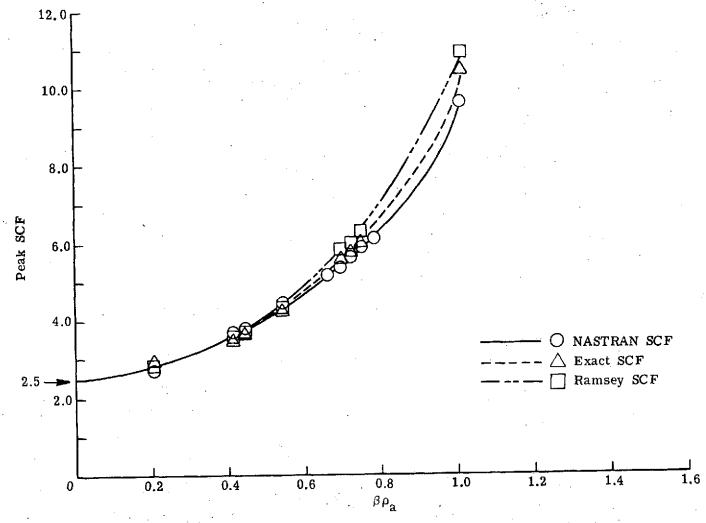

Figure 5.3.1.- Effect of shell thickness and curvature, and hole size $(\beta \rho_a)$ on peak SCF for shell and force (t=0) configurations.

(b) THICK PIPE (
$$\frac{\rho_0}{t}$$
< 10)

slightly more accurate than the thin pipe results for both the formula (\pm 12%) and NASTRAN (-4%) as compared to the "exact" (1,11;24) results. For the same category, it is shown in Table 5.3.3(b) that the formula comparisons are below the experimental (17) by 19%. The first four configurations in Table 5.3.3(b) and the last three in Table 5.3.2(b) have $\rho_a/T \le 1.1$. At the end of Chapter IV, it was stated that transverse shear effects would be negligible provided $\rho_a/T > 3.0$ and $R/T \ge 25.0$. Both of these requirements are violated. Therefore, the low SCF from the formula is to be expected since the hole is too small and/or the shell too thick. Therefore, the overall accuracy of the formula for a thin shell and thick pipe is approximately $\pm 12\%$ by not including the configurations where $\rho_a/T < 1.1$ and $\frac{R}{m} < 14.7$.

The theoretical comparison of Eringen's $^{(11)}$ analytical results to the formula for the shell and pipe configurations is presented in Table 5.3.4. The accuracy between the two of $\pm 8\%$ is remarkable. The cases are tabulated by per cent difference from lowest to highest. These are the only valid cases from this report. The others violated all four of his theoretical requirements:

R/T > 10, ρ_0/t > 10, $\beta\rho_0$ < 0.5, and $\rho_0/R \le 1/3$.

Tables 5.3.5 and 5.3.6 present numerous experimental (8,11,16,17,19,21,22,135) configurations for thick

shells and pipes. The comparison between the formula and these experiments are presented to illustrate the need to impose the restrictions presented in Section 5.2. The differences between the formula and thick shell and pipe experimental results are -22% to +17%.

The shell/pipe/pad (top and bottom) configurations (Figure 4.4.1) are listed in Tables 5.3.7 through 5.3.9. The same categories as shell and pipe are maintained for the shell/pipe/pad comparisons. The comparisons are for NASTRAN, formula, and six experimental results. The thin shell and pipe $(\frac{R}{T} \text{ and } \frac{\rho_0}{t} \ge 10)$ cylinders with a top pad are presented in Table 5.3.7. The differences of the formula as compared to NASTRAN for the top pad are -15.9% to 11.4%. The thin shell and pipe with a bottom pad are listed in Table 5.3.8. The formula differences for the bottom pad as compared to NASTRAN and the one experimental result (24) are -16.1% to +3.2%. The thick pipe $(\frac{\rho}{t} < 10)$, thin/thick shell, and pad results are shown in Table 5.3.9.

The last three configurations in Table 5.3.7 and first three in Table 5.3.9 have only one difference - Poisson's ratio. There are 0.8% (Table 5.3.7) and 1.0% (Table 5.3.9) differences between the NASTRAN SCF for all \mathbf{v} 's = 0.3 and for \mathbf{v} = 0.3, \mathbf{v}_p = \mathbf{v}_{pad} = 0.5. Based on these six examples, the formula only provides a different Poisson's ratio for

(b) Thin Shell

the shell and pipe. The overall differences between NASTRAN and the formula for the shell/pipe/and pad (top and bottom) are -16.1% to 11.4%. The comparisons between experiments and the formula are -9.3% to 1.7% differences.

The NASTRAN/formula comparisons for shell, pipe, and pads configurations (see Figure 4.5.1) are presented in Table 5.3.10. All of these results are for thin shell and pipe except the three thick pipe configurations denoted by an asterisk (*) in the "exact" column. The "two pad" experimental investigation presented in Chapter III is also included. The configuration that is presented in Appendix A as a representative NASTRAN program is indicated by "Appendix A" in the "exact" column. Most of the SCF values obtained are for configurations that represent current pressure vessel analysis, design, and construction - i.e. identical inner and outer pad thicknesses and outside radii. The fifth through the seventh configurations in Table 5.3.10 have different geometries for the two pads. The accuracy of the formula for these examples is approximately +6%. The overall accuracy is -8.91% to +14.65% difference.

Figures 5.3.2 and 5.3.3 are representative of the manner in which peak stress concentration factors (SCF) for a pressurized cylindrical shell are affected by (1) thickness and curvature of shell and hole size $(\beta \rho_a)$, and (2) reinforcement configurations (pipe and pipe/pad(s)).

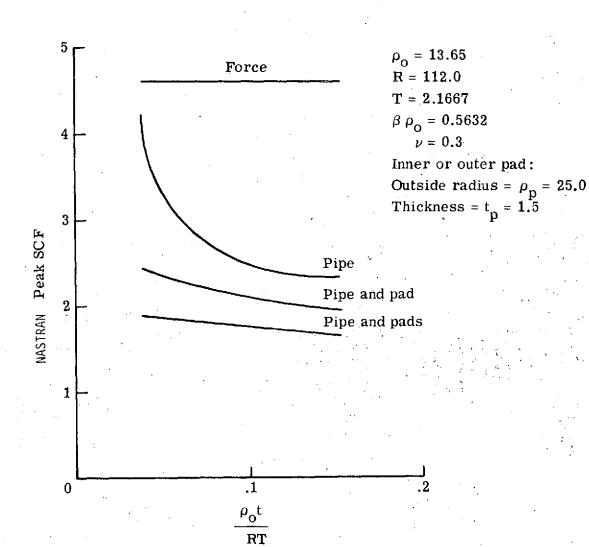

Figure 5.3.2.- Effect of reinforcement (pipe and pipe/pad(s) configurations) on peak SCF for a pressurized cylindrical shell ($\beta \rho_0 = 0.5632$).

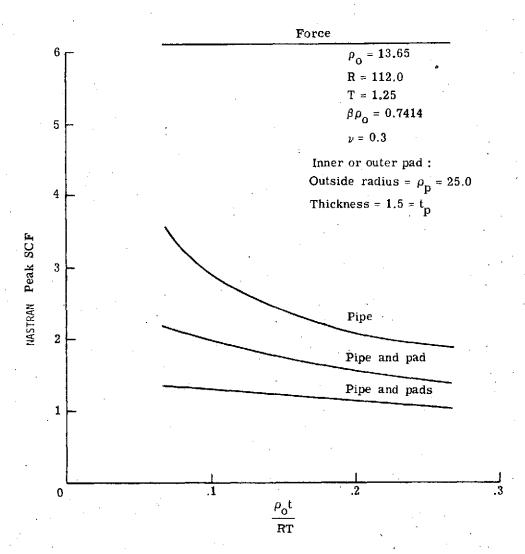

Figure 5.3,3,- Effect of reinforcement (pipe and pipe/pad(s) configurations) on peak SCF for a pressurized cylindrical shell ($\beta\rho_0$ = .7414).

The force value in each figure was obtained from Figure 5.3.1. For both $\beta\rho_{0}=0.5632$ and $\beta\rho_{0}=0.7414$, the largest reduction in SCF is due to the reinforcement either offered from a "thick" pipe or from a "thin" pipe and one pad. This was typical of all results obtained. The SCF reduction due to a second pad was always minor in comparison to that obtained from a thick pipe or pipe/pad configuration. Although more pronounced for the smaller $\beta\rho_{0}$ (analogons to smaller hole), the peak stress concentration factors for the shell and pipe rapidly increase as $\frac{\rho_{0}t}{RT}$ decreases. This is indicative of the transverse shear effects (small ρ_{0}/T). Extension of the pipe and pad(s) curves to the peak SCF ordinate at t=0 yields the answer for the shell/force/ pad(s) configurations.

5.4 Force and Pad(s)

It was stressed in Chapter IV that the primary thrust of the analysis would be for the cases previously presented. Another type of configuration can be solved by the formula. This is for t = 0 and the hole reinforced by one or two pads. Table 5.4.1 contains comparisons of formula to NASTRAN results for thin, pressurized, cylindrical shells with pad(s) reinforcing a hole covered with a membrane (force only). This type of configuration is identical to Figure 4.2.1 plus one or two reinforcing pads. The formula results for

the top pad configuration have an accuracy of approximately $\pm 9.7\%$, whereas all of bottom pad stress concentration factors were 5% to 13% above the NASTRAN results. All of the force and pads formula results were below the NASTRAN answers. The difference range is -10.2% to -1.3%.

CHAPTER VI

DISCUSSION OF RESULTS

This study provides numerical predictions of peak stress concentration factors around nonreinforced and reinforced penetrations. Numerical results have been correlated with published formulas, as well as theoretical and experimental Most of the configurations have been for thin results. shells, and all are based on linear elastic structures. Some thick shell NASTRAN and published results were obtained. An accuracy study was made of the finite element program for each of the configurations considered important in pressure vessel technology. A formula was developed to predict the peak stress concentration factor for analysis and/or design in conjunction with the ASME Pressure Vessel The accuracy of the empirical formula is determined by comparing to numerical, theoretical, and experimental data.

The peak stress concentration factors (SCF) presented in Chapter V have confirmed that the 3.3 limit imposed by the ASME Code is indeed conservative for the vast majority of cases. The peak SCF results due to reinforcement (pipe or pad(s)) around a circular penetration in cylindrical, pressurized shells suggest a different number. If fact, 78.5% (124 out of 158) of the shell and pipe configurations

were less than 3.3. Using the procedure for a well designed penetration presented in Ref. (25) and shown approximately in Figure 5.2.1, the one pad problems (32) were checked for ASME Code reinforcement requirements. The six "coded" pad configurations are as follows: Table 5.3.7, first two t = 1.25 configurations (SCF = 2.134 and 1.868); Table 5.3.8, second and fourth configurations (SCF = 1.824 and 1.827); and Table 5.3.9, first T = 1.0 and T = 1.25 configurations (SCF = 2.07 and 1.379). All of the other 26 one pad configurations were not "coded" and yet had peak SCF results equal to or below 3.0. The two pad problems were mostly "coded" (by choice). The seven configurations in Table 5.3.10 which are not "coded" are the first five examples and those with T = 1.2 and T = 4.48. For the two pad configuration only one of the twenty problems had a peak SCF outside of the range of 1.0 to 2.0. This was a "coded" pads configuration (T = 2.0 and R/T = 25) with a peak SCF = 2.177. Based on these results, a "thick" pipe (Figure 5.3.3), "coded" pad, or two pad configuration would have a peak SCF of about 2.2 (2/3 of the 3.3 limit), whereas the shell and pipe configuration could achieve the "well designed penetration" (SCF = 3.3) definition.

All of the peak SCF results are summarized in Table 6.1 according to thick, thin, or membrane shell definitions.

The NASTRAN results compared to published values, +17.4% to

-8.9%, are high, as expected, when the membrane category is approached and low for an almost thick shell. This same general trend is true for the shell and pipe examples. The thin shell and pipe NASTRAN accuracy is +8.8% to -14.0%. There is not enough data to determine any trend for the pipe and pad(s) NASTRAN results.

The formula results compare favorably with NASTRAN and the published "experimental, theoretical, and numerical" data. The results for individual comparisons to NASTRAN and "exact" are shown in Table 6.1 by categories. The thin shell approximate percent difference results are as follows: force, $\pm 4.8\%$; pipe, $\pm 14.4\%$; pipe and pad, $\pm 13.7\%$; pipe and pads, $\pm 11.7\%$; force and top pad, $\pm 9.7\%$; force and bottom pad, 13%; and force and pads, -10%.

One application of this formula is to an ASME Code "hillside" (elliptical hole) penetration. The amplification factor by the code for this penetration is $1 + 2 \sin^2$ (the angle the axis of the pipe makes with the normal to the shell wall). Two experimental results were obtained. (15,38) This amplification factor was multiplied times the (circular) peak SCF from the formula to obtain the following comparisons:

1. "Exact" SCF = $1.840^{(15)}$ vs formula SCF = 1.826 (-0.8% difference) for ρ_a = 4.782, R = 19.0, T = 1.0, t = 0.593, ρ_{op} = 7.438, t = 11.625 v = 0.3, and the angle = 20° .

2. "Exact SCF = $2.897^{(38)}$ vs formula SCF = $2.897^{(9.98)}$ difference) for ρ_a = 11.94, R = 69.185, T = 1.995, ν = 0.3, and the angle = 45° .

, i.e.

CHAPTER VII SUMMARY

The effect on stresses in a cylindrical shell with a circular penetration subject to internal pressure has been investigated. A general purpose finite element (NASTRAN) computer program was utilized to supplement the limited data for reinforced penetrations. A mesh generation computer program was developed to "automatically" punch input cards in the format acceptable to NASTRAN. This program is readily adaptable to solving a general finite element shell problem. The NASTRAN compatibility equations for a shell/pipe or a shell/pipe/pad(s) configuration were successfully implemented. This provides a quick access to a detail SCF for a reinforced nozzle in a pressure vessel. The accuracy of the finite element model has been investigated. Moreover, for an immediate, approximate solution to this complex problem, the formula may be utilized.

The formula is (1) more accurate than the published nonreinforced penetration formulas and, (2) believed to be the only formula applicable for reinforced penetrations in pressurized cylindrical shells. The accuracy of the formula was determined by comparing to the numerical, theoretical, and experimental data. It has been shown that the shell and pipe configuration can easily achieve the

"well designed penetration" (SCF = 3.3) definition. A reinforced penetration (thick pipe, coded pad, or two pads) would have a peak SCF of about 2.2 (2/3 of the 3.3 limit).

This formula can be used to obtain the peak stress concentration factor for reinforced or nonreinforced penetrations in pressurized cylindrical shells. Thus, in the analysis and design of a new pressure vessel, the formula could save (1) the time to perform a detail analysis; (2) the time to construct the reinforcing pad(s) which are not always required; and (3) the extra cost of materials, fabrication, and weld examination. Also, fatigue analyses can be performed to obtain the remaining life in the penetration welds of cylindrical shells. If the remaining life is small or exhausted, then a nondestructive examination (NDE, i.e. magnetic particle, ultrasonic, or radiographic) and/or repair of these penetrations would be performed.

This type of verification (analyses and partial field work) of structural integrity of welds is invaluable since it is not practical to examine and/or repair every weld in all pressure vessels. The economics and feasibility of a validation program (6000 pressure components at Langley Research Center within the next five years) would be impractical without this formula. There have been six tunnels (pressure vessels) for which this procedure (formula

and NDE) has been followed. For example, the world's first known "cryogenic" tunnel utilizing nitrogen as the working medium (40) incorporated this formula in obtaining the expected life of this facility.
